Introduction:

This project studies how Finland's population has changed over time and how it may develop in the near future. I used open population data covering 1990 to 2025 and built a machine learning workflow to estimate future population values for 2030 to 2040.

The main goal was not only to plot the historical trend, but also to prepare the data in a usable format, test a prediction model, and compare growth patterns across different areas.

2. Data Preparation:

I started by loading the raw CSV file and checking its structure. The source table includes area names and yearly population values, so I first renamed the columns into simpler labels.

After that, I filtered the dataset to keep only the end-of-year population measure. I then reshaped the data from wide format into long format. In the long table, each row represents one area in one year.

Finally, I converted the year field into integers and the population values into numeric format. This made the dataset ready for visualization and modeling.

Photos of VS Code:

```
df = df.rename(columns={
    "Alue": "Region",
    "Tiedot": "Indicator"
})

df = df[df["Indicator"] == "Väestö 31.12."].copy()
df.head()
```

[22]

Comparison:

The result I showed here, is from VS Code and CSC supercomputer

But if you check both environments produced the same dataset output, which confirms that the data cleaning and preprocessing steps were performed properly.

And there is no difference in values; only the execution environment is different.

CSC may provide faster performance for large-scale computations.

3. Population Trend Analysis

Using the Finland total row, I plotted the population trend from 1990 to 2025. The graph shows a generally upward direction over time, although the speed of growth is not identical every year.

This visualization gives a quick national overview and works as the starting point for the forecasting section.

Photos of VS Code:

```
plt.figure(figsize=(8, 5))
plt.plot(country["Year"], country["Population"], marker="o")
plt.title("Finland Population Trend 1990-2025")
plt.xlabel("Year")
plt.ylabel("Population")
plt.grid(True)
plt.show()
```

[26]

Photos of Supercomputer:

```
[6]: plt.figure(figsize=(8,5))
     plt.plot(country["Year"], country["Population"], marker="o")

     plt.title("Finland Population Trend 1990-2025")

     plt.xlabel("Year")
     plt.ylabel("Population")
     plt.grid(True)
     plt.show()
```

4. Machine Learning Preparation

I have prepared the data for the model by selecting the year as the input and the population as the value to use it for prediction.

After that, I have normalized the data using the average value and standard deviation. This step has helped me to improve the performance of the model and allows it to learn more efficiently.

5. Model Building

I used an MLPRegressor neural network model. The model learns from historical population data and tries to capture the relationship between time and total population.

The purpose of the model is simple: use past observations to estimate future values.

Photos of VS Code:

```
model = MLPRegressor(
    hidden_layer_sizes=(16,),
    activation="relu",
    solver="adam",
    learning_rate_init=0.01,
    max_iter=3000,
    random_state=42
)
model
```

[28]

```
MLPRegressor
▶ Parameters
```

Photos of Supercomputer:

Build TensorFlow regression model: In this step, I have created a neural network model using MLPRegressor:

I have used one hidden layer with 16 neurons Then, I have use ReLU as the activation function Then,I have used Adam as the optimizer Then, I set the learning rate to 0.01 Then, I train the model for a maximum of 3000 iterations Finally, I set a random state to get the same results every time

[8]:
```
from sklearn.neural_network import MLPRegressor

model = MLPRegressor(
    hidden_layer_sizes=(16,),
    activation="relu",
    solver="adam",
    learning_rate_init=0.01,
    max_iter=3000,
    random_state=42
)
```

Train the model :

In this step, I have trained the neural network model:

I have used the scaled input data (X_scaled) and scaled target data (y_scaled)

[9]:
```
model.fit(X_scaled, y_scaled)
```

[9]:
```
MLPRegressor
▶ Parameters
```

Evaluate model on historical data : In this step, I check how well my model is performing:

I use the trained model to make predictions on the training data I calculate the loss using Mean Squared Error (MSE) I also calculate the MAE (Mean Absolute Error)

Results : The loss shows how much error the model has (lower is better) The MAE shows the average difference between predicted and actual values

6. Model Evalution

After training, I used the model to predict the historical data and measured the average error. The loss and MAE values were small, which suggests that the model follows the historical curve reasonably well.

This does not prove perfect forecasting, but it shows that the model has learned the overall pattern in the national series.**Photos of VS Code:**

Results : The loss shows how much error the model has (lower is better) The MAE shows the average difference between predicted and actual values

```python
train_preds = model.predict(X_scaled)

loss = np.mean((train_preds - y_scaled) ** 2)
mae = np.mean(np.abs(train_preds - y_scaled))

print("Loss:", loss)
print("MAE (scaled):", mae)
```

✓ 0.0s

```
Loss: 0.01707506806203566
MAE (scaled): 0.1031003282584641
```

Photos of Supercomputer:

Results : The loss shows how much error the model has (lower is better) The MAE shows the average difference between predicted and actual values

```python
train_preds = model.predict(X_scaled)

loss = np.mean((train_preds - y_scaled) ** 2)
mae = np.mean(np.abs(train_preds - y_scaled))

print("Loss:", loss)
print("MAE (scaled):", mae)
```

```
Loss: 0.01707506806203566
MAE (scaled): 0.1031003282584641
```

7. Forecast for 2030–2040 :

The trained model was then used to predict Finland's future population for the years 2030 to 2040. The forecast suggests gradual continued growth.

I also plotted the historical values together with the forecast so the transition from observed data to predicted data is easy to understand.
Photos of VS Code:

```python
plt.figure(figsize=(9, 5))

plt.plot(
    country["Year"],
    country["Population"],
    marker="o",
    label="Actual population"
)

plt.plot(
    forecast_df["Year"],
    forecast_df["Predicted Population"],
    marker="o",
    linestyle="--",
    label="Forecast 2030-2040"
)

plt.title("Finland Population Forecast 2030-2040")
plt.xlabel("Year")
plt.ylabel("Population")
plt.legend()
plt.grid(True)
plt.show()
```

```python
future_years = np.arange(2030, 2041)
future_scaled = ((future_years - X_mean) / X_std).reshape(-1, 1)

future_preds_scaled = model.predict(future_scaled)
future_preds = future_preds_scaled * y_std + y_mean

forecast_df = pd.DataFrame({
    "Year": future_years,
    "Predicted Population": future_preds.astype(int)
})

forecast_csv_path = Path("finland_population_forecast_2030_2040.csv")
forecast_df.to_csv(forecast_csv_path, index=False)

print("Saved forecast CSV to:", forecast_csv_path.resolve())

8. Growth Analysis by Area

To compare areas, I calculated the yearly percentage change in population for each area and then summarized the average growth rate.

This made it possible to identify places with stronger long-term growth and areas with long-term decline. These differences matter because fast-growing places may need more housing and infrastructure, while shrinking areas may face demographic pressure and service challenges.

Photos of VS Code:

9. Anomaly Detection

I measured year-to-year changes in the growth rate and marked unusual values using a three-standard-deviation rule.

These anomalies can highlight years when population movement was stronger than usual or when a region behaved differently from its normal pattern.
For VS Code :

```python
anomalies = df_long[df_long["Anomaly"]].copy()
anomalies.head(20)
```

	Region	Indicator	Year	Population	Growth Rate	Growth Change	Anomaly

10. Clustering Analysis :

I grouped areas using average population and average growth rate. Before clustering, I scaled the variables so that neither one would dominate the grouping.

Then I applied K-Means with three clusters. The cluster plot helps show which areas are similar in size and growth behavior.
Photos of VS Code:

```python
cluster_data = (
    df_long.groupby("Region")
    .agg(
        avg_population=("Population", "mean"),
        avg_growth=("Growth Rate", "mean")
    )
    .dropna()
)

scaler = StandardScaler()
cluster_scaled = scaler.fit_transform(cluster_data)

kmeans = KMeans(n_clusters=3, random_state=42, n_init=10)
cluster_data["Cluster"] = kmeans.fit_predict(cluster_scaled)

cluster_data.head()
```

	avg_population	avg_growth	Cluster
Region			
Akaa	16443.722222	0.000686	1
Alajärvi	10670.388889	-0.008143	0
Alavieska	2792.611111	-0.007185	0
Alavus	12500.138889	-0.007377	0
Asikkala	8464.555556	-0.003349	0

```python
plt.figure(figsize=(8, 5))
plt.scatter(
    cluster_data["avg_population"],
    cluster_data["avg_growth"],
    c=cluster_data["Cluster"]
)
plt.title("Municipality / Region Clusters by Population and Growth")
plt.xlabel("Average Population")
plt.ylabel("Average Growth Rate")
plt.grid(True)
plt.show()
```

For Supercomputer:

[35]:
```
cluster_data = (
    df_long.groupby("Region")
    .agg(
        avg_population=("Population", "mean"),
        avg_growth=("Growth Rate", "mean")
    )
    .dropna()
)

scaler = StandardScaler()
cluster_scaled = scaler.fit_transform(cluster_data)

kmeans = KMeans(n_clusters=3, random_state=42, n_init=10)
cluster_data["Cluster"] = kmeans.fit_predict(cluster_scaled)

cluster_data.head()
```

[35]:

Region	avg_population	avg_growth	Cluster
Akaa	16443.722222	0.000686	1
Alajärvi	10670.388889	-0.008143	0
Alavieska	2792.611111	-0.007185	0
Alavus	12500.138889	-0.007377	0
Asikkala	8464.555556	-0.003349	0

[36]:
```
plt.figure(figsize=(8, 5))
plt.scatter(
    cluster_data["avg_population"],
    cluster_data["avg_growth"],
    c=cluster_data["Cluster"]
)
plt.title("Municipality / Region Clusters by Population and Growth")
plt.xlabel("Average Population")
plt.ylabel("Average Growth Rate")
plt.grid(True)
plt.show()
```

11. Comparison: VS Code vs CSC :

I ran the same type of workflow in both VS Code and CSC-style environments. The numerical outputs should remain very close when the same code, same data, and same package behavior are used.

The practical difference is mostly in the environment:
- VS Code is easier for writing and editing
- CSC is more useful when computation becomes larger or heavier

VS Code Forecast graph ;

```
plt.figure(figsize=(9, 5))

plt.plot(
    country["Year"],
    country["Population"],
    marker="o",
    label="Actual population"
)

plt.plot(
    forecast_df["Year"],
    forecast_df["Predicted Population"],
    marker="o",
    linestyle="--",
    label="Forecast 2030-2040"
)

plt.title("Finland Population Forecast 2030-2040")
plt.xlabel("Year")
plt.ylabel("Population")
plt.legend()
plt.grid(True)
plt.show()
```

Supercomputer Forecast Graph :

```
[32]: plt.figure(figsize=(9, 5))

plt.plot(
    country["Year"],
    country["Population"],
    marker="o",
    label="Actual population"
)

plt.plot(
    forecast_df["Year"],
    forecast_df["Predicted Population"],
    marker="o",
    linestyle="--",
    label="Forecast 2030-2040"
)

plt.title("Finland Population Forecast 2030-2040")
plt.xlabel("Year")
plt.ylabel("Population")
plt.legend()
plt.grid(True)
plt.show()
```

VS Code Loss/MAE:

```
train_preds = model.predict(X_scaled)

loss = np.mean((train_preds - y_scaled) ** 2)
mae = np.mean(np.abs(train_preds - y_scaled))

print("Loss:", loss)
print("MAE (scaled):", mae)
[30]

Loss: 0.01707506806203566
MAE (scaled): 0.1031003282584641
```

CSC Loss/MAE :

```
[30]: train_preds = model.predict(X_scaled)

      loss = np.mean((train_preds - y_scaled) ** 2)
      mae = np.mean(np.abs(train_preds - y_scaled))

      print("Loss:", loss)
      print("MAE (scaled):", mae)

      Loss: 0.01707506806203566
      MAE (scaled): 0.1031003282584641
```

Conclusion

Overall, the project shows that Finland's population has generally increased over the observed period, and the model projects further growth into 2040.

At the same time, the regional analysis shows that not all areas move in the same direction. Some places grow faster, some are stable, and others decline. That is why growth analysis, anomaly detection, and clustering are useful additions to the national forecast.
